Toy Functionality Toy Functionality toy functionalities are designed to improve the functionality of toys. Toy functionalities vary from additional functionalities such as bendable construction, to animal behavior, intelligence, sensor, or lighting. Functionality is a critical element of toy design. How a toy feels and responds to your child's touch is what will make it more valuable to them and lead to continued play. Some toy functionalities such as intelligence, sensation, or emotion can also play a critical role in the overall experience and success of your child's play. All of these components need to be considered when designing a toy that will be effective for them. We currently support three areas of toy functionality: Bendable Toy Functionalities Bendable toys are toys that can be placed in a variety of configurations to create engaging and exciting toys. Bendable toy functionalities can enhance the way toys play and interact with your child. An example of a popular toy that uses bendable functionality is the Slinky, which has been in continuous production for over 100 years. It has been used in toys, children's books, educational toys, and has even been a film prop. The bendable toy functionality of the Slinky allows it to be used as a toy, but also to be used as a tool. It is fun to play with and allows your child to help create shapes and structures. Many toys are not bendable, but we are creating new types of functionality that allow toys to behave in new ways. Animal Behaviors Some of the most popular toys on the market are animal toys. We've created functions and benefits for animals that have never been available before. Animals can have strong emotional responses to toys and activities. When these emotions are provided in a toy, it can make the experience more dynamic for your child.

Fibrinogen: an update on its role in the coagulation cascade. Human fibrinogen is a 340 kDa glycoprotein composed of three pairs of nonidentical polypeptide chains, which become covalently linked together by a process of enzymatic polymerization to form an insoluble fibrin clot. This molecule is synthesized in the liver and in the megakaryocytes, which are located in the bone marrow. Studies on fibrinogen synthesis in the liver have shown that the α , β , and γ polypeptide chains are independently regulated; the regulation is however not complete and the synthesis of only one of the three chains is affected by changes in the nutritional status of the patient. The γ -chain synthesis is controlled by an independent regulatory pathway which is subjected to a positive (growth factors and cytokines) and a negative feedback (APC-C3 convertase). The other two chains are regulated by the APC-C3 convertase, which is responsible for the inhibitory feedback on the synthesis of the β -chain. The interaction of these three chains with each other is also regulated, but only the γ chain forms a high-molecular-weight complex with the α and β chains, the latter two chains remaining linked to form a low-molecular-weight complex. The formation of the fibrin clot is regulated by a series of enzymes and it is not until the final moment of the coagulation cascade that fibrin is formed. Fibrinogen is degraded by the plasmin/plasminogen system. In this review the role of fibrinogen in the coagulation cascade is discussed. 6-year-old Girl Killed in Western Mass.
